ILCOR Advisory Statement

Temperature Management After Cardiac Arrest

An Advisory Statement by the Advanced Life Support Task Force of the International Liaison Committee on Resuscitation and the American Heart Association Emergency Cardiovascular Care Committee and the Council on Cardiopulmonary, Critical Care, Perioperative and Resuscitation

Abstract/Summary

For more than a decade, mild induced hypothermia (32°C–34°C) has been standard of care for patients remaining comatose after resuscitation from out-of-hospital cardiac arrest with an initial shockable rhythm, and this has been extrapolated to survivors of cardiac arrest with initially nonshockable rhythms and to patients with in-hospital cardiac arrest. Two randomized trials published in 2002 reported a survival and neurologic benefit with mild-induced hypothermia. One recent randomized trial reported similar outcomes in patients treated with targeted temperature management at either 33°C or 36°C. In response to these new data, the International Liaison Committee on Resuscitation (ILCOR) Advanced Life Support (ALS) Task Force performed a systematic review to evaluate 3 key questions: (1) Should mild induced hypothermia (or some form of targeted temperature management) be used in comatose post-cardiac arrest patients? (2) If used, what is the ideal timing of the intervention? (3) If used, what is the ideal duration of the intervention? The Task Force used GRADE (Grading of Recommendations Assessment, Development and Evaluation) methodology to assess and summarize the evidence, and to provide a consensus on science statement and treatment recommendations. The Task Force recommends targeted temperature management for adults with out-of-hospital cardiac arrest with an initial shockable rhythm at a constant temperature between 32°C and 36°C for at least 24 hours. Similar suggestions are made for out-of-hospital cardiac arrest with a nonshockable rhythm and in-hospital cardiac arrest. The Task Force recommends against prehospital cooling with rapid infusion of large volumes of cold intravenous fluid. Additional and specific recommendations are provided in the document.
**Introduction**

Sudden cardiac arrest is one of the leading causes of death in adults around the world. Although incidence varies from country to country, cardiac arrest affects several million people annually, with an average survival rate of <10%. In patients who remain comatose after cardiac arrest, the post-cardiac arrest syndrome is a complex set of pathophysiological processes consisting of brain injury, myocardial depression, and systemic ischemia-reperfusion injury as well as ongoing injury caused by the precipitating etiology of the arrest.

For more than a decade, mild induced hypothermia (32°C–34°C) has been the cornerstone of post-cardiac arrest care. Mild to moderate hypothermia induced after global brain ischemia or cardiac arrest was initially evaluated in animal models that showed improved neurological function for those receiving induced hypothermia. After 2 human randomized trials published in 2002, the International Liaison Committee on Resuscitation (ILCOR) recommended in 2003 that “unconscious adult patients with spontaneous circulation after out-of-hospital cardiac arrest (OHCA) should be cooled to 32°C to 34°C for 12 to 24 hours when the initial rhythm was VF” [ventricular fibrillation] and that “such cooling may also be beneficial for other rhythms or in-hospital cardiac arrest.” Similar recommendations were provided in the 2010 International Consensus on Cardiopulmonary Resuscitation and Emergency Cardiovascular Care Science With Treatment Recommendations.

Recently, a prospective randomized trial comparing a targeted temperature of 33°C with 36°C for a large group of OHCA patients found that both groups had similar mortality (primary end point) and neurologic outcome at 180 days. As a result of that trial, there has been debate about the optimal target temperature for post-cardiac arrest patients. To address the evolving science of targeted temperature management (defined as an active therapy to achieve and
maintain a specific target temperature for a defined duration), the ILCOR Advanced Life Support (ALS) Task Force conducted an evidence review and created an updated position paper to address 3 key questions about temperature management in the post-cardiac arrest patient:

1. For patients who remain comatose after return of spontaneous circulation (ROSC), should targeted temperature management be used?
2. If targeted temperature management is used, what is the optimal timing of initiation?
3. If targeted temperature management is used, what is the optimal duration of therapy?

To address these questions, the Task Force created formal PICO (Population, Intervention, Comparison, and Outcome) questions and performed a comprehensive literature search. The Task Force evaluated, compiled, and summarized the evidence by using GRADE (Grading of Recommendations Assessment, Development and Evaluation; www.gradeworkinggroup.org) methodology and performed meta-analyses when appropriate. The Task Force then created a consensus statement by considering the available evidence as well as balancing benefits and harms to guide the final recommendations.

**Methods**

**Overview**

We conducted a systematic review and, when appropriate, meta-analyses for 3 distinct questions about temperature management (outlined in the section on “Questions Asked”). We completed a bias assessment for all included studies and then used GRADE methodology to evaluate this evidence and develop treatment recommendations. The outcomes of interest were defined and
prioritized by the ILCOR ALS Task Force, as part of the evidence review process for the 2015 ILCOR guidelines.

Questions Asked

The literature searches were designed to address the following 3 PICO\textsuperscript{15} questions:

1. Among patients with ROSC after cardiac arrest in any setting (P), does inducing mild hypothermia (target temperature 32°C–34°C) (I), compared with no targeted temperature management (C), change survival with favorable neurologic/functional outcome at discharge, 30 days, 60 days, 180 days, and/or 1 year or survival only at discharge, 30 days, 60 days, 180 days, and/or 1 year (O)?

2. Among patients with ROSC after cardiac arrest in any setting (P), does induction of hypothermia before some time point (eg, 1 hour after ROSC or before hospital arrival) (I), compared with induction of hypothermia after that time point (C), change survival with favorable neurologic/functional outcome at discharge, 30 days, 60 days, 180 days, and/or 1 year or survival only at discharge, 30 days, 60 days, 180 days, and/or 1 year (O)?

3. Among patients with ROSC after cardiac arrest in any setting (P), does induction and maintenance of hypothermia for any duration other than 24 hours (I), compared with induction and maintenance of hypothermia for a duration of 24 hours (C), change survival with favorable neurologic/functional outcome at discharge, 30 days, 60 days, 180 days, and/or 1 year or survival only at discharge, 30 days, 60 days, 180 days, and/or 1 year (O)?
Selection of Studies

Information specialists searched PubMed, EMBASE, and the Cochrane Library in December 2013 (questions #2 and #3) and January 2014 (question #1) and again in December 2014 by using the search terms outlined in Appendix A in the online-only Data Supplement.

Data Selection and Extraction

Two reviewers independently screened titles and abstracts that resulted from the search for studies that addressed the question posed by each PICO. Inclusion criteria within each question were chosen on the basis of the amount and type of evidence available. The entire Task Force approved each set of criteria. Disagreement on individual studies was settled via consensus between the reviewers and a facilitator from the Task Force.

- Question #1: For patient populations in which randomized control trials (RCTs) were available (ie, out-of-hospital shockable cardiac arrest), only RCTs were included. Otherwise, observational studies were included for the 2 patient populations in which there were no RCT data: in-hospital cardiac arrest (IHCA) and OHCA with an initial nonshockable rhythm. We did not include studies without a comparator group, studies that did not report separate outcomes for shockable and nonshockable rhythms, or studies that only reported unadjusted outcomes. We chose to exclude studies with a pre-post design because of the significant changes in post-cardiac arrest care over the past several years and the consequent danger of significant confounding based on year of arrest.

- Question #2: Only human RCTs were included. Given the number of human RCTs available for review, observational data was excluded.
• Question #3: Given the lack of human RCT data, all studies with a comparator group were included. Case reports/series were not included. Studies published only in abstract form were excluded from all 3 questions because of the risk of incomplete reporting. There were no exclusions based on language. Articles were initially included based on title and/or abstract. Subsequently, the manuscript was reviewed to determine whether the article addressed the PICO question and whether all inclusion and no exclusion criteria were met. Inclusion of animal studies were beyond the scope of the current manuscript although we recognize that animal studies have and will continue to provide valuable preliminary and mechanistic data.

**Bias Assessment and GRADE Methodology**

All included RCTs were assessed for bias based on criteria from the *Cochrane Handbook for Systematic Reviews of Interventions*. Briefly, RCTs were assessed on the adequacy of allocation generation, allocation concealment, blinding of participants, blinding of outcome assessors, completeness of follow-up, selectivity of outcome reporting, and a final category for “other” sources of bias. Observational studies were assessed for the presence of appropriate eligibility criteria, clear exposure and outcome definitions, confounding, and completeness of follow-up. The results of the bias assessments are detailed in the Appendixes in the [online-only Data Supplement](http://circ.ahajournals.org/). The overall quality of evidence was summarized using the GRADE approach and online tools. Briefly, the GRADE approach assesses the combined quality of the evidence, or confidence in the estimates of effect, across individual outcomes by evaluation for risk of bias, indirectness, imprecision and inconsistency, as well as other considerations of the included studies. In each category the evidence for a given outcome can be rated as being free of serious
concerns or downgraded by 1 or 2 levels for serious or very serious concerns respectively. The quality of evidence across each outcome is rated as very low, low, moderate or high based on these considerations. RCTs start as high quality and observational studies start as low quality and can then be upgraded or downgraded based on the above criteria. The details of the current GRADE evaluations are provided in the Appendixes in the online-only Data Supplement. The GRADE approach, inclusive of definitions and details of the above, is described in extensive detail at www.gradeworkinggroup.org. In this manuscript, for the sake of consistency we chose to report mortality and poor neurological outcome throughout the manuscript, acknowledging that this differs from the phrasing of the PICO question outcomes in some cases.

Meta-analysis

Meta-analyses were conducted when the included RCTs were judged to be comparable in terms of patients, interventions, comparisons, and outcomes. To be conservative, we assumed a considerable amount of heterogeneity and used random-effects models for all analyses. All plots and estimates were calculated with RevMan version 5.2, and data are summarized as relative risks (RR) or odds ratios (OR) with 95% confidence intervals (95% CI).

Development of the Treatment Recommendations

The GRADE approach was used to grade the strength of recommendations and inform the language of the treatment recommendations. The evidence reviewers drafted a statement of the consensus on science and treatment recommendations, which was then reviewed and revised by the Task Force through an iterative process. The final advisory statement was voted on and
approved by the members of the Task Force. A majority rule was applied, though the vote was close to unanimous for all recommendations.

**Results and Recommendations (Consensus on Science)**

*Question #1: Does Mild Hypothermia Compared With No Targeted Temperature Management Improve Outcome?*

**Evidence**

The search yielded a total of 5,045 studies. Of these, 6 RCTs and 5 observational studies were included for bias assessment (online-only Data Supplement; see Appendix B for study selection flow diagram, Appendix C for study overview, and Appendix D for bias assessment). One small feasibility RCT was not included in the bias assessment because the intervention group received cooling only until the target temperature was reached or for 4 hours, whichever came first. After bias assessment, 1 RCT was not considered further because of a high risk of bias as outlined in Appendix D of the online-only Data Supplement. We used the remaining 5 RCTs to assess the evidence for temperature management in OHCA. Five observational studies addressed the evidence for targeted temperature management for IHCA and OHCA with an initial nonshockable rhythm. We organized the available evidence into separate but related categories:

1. Evidence to support targeted temperature management versus no targeted temperature management for
   a. Adult patients with ROSC after OHCA with an initially shockable rhythm
   b. Adult patients with ROSC after OHCA with an initially nonshockable rhythm
   c. Adult patients with ROSC after IHCA with any initial rhythm
2. In patients for whom targeted temperature management is performed, what is the ideal target temperature?

**OHCA With an Initial Shockable Rhythm**

One RCT and 1 quasi-randomized trial enrolling a total of 352 patients provided overall low-quality evidence for decreased poor neurologic outcome in patients with OHCA with ventricular fibrillation (VF) or pulseless ventricular tachycardia (VT) as an initial rhythm who were cooled to 32°C to 34°C compared with no cooling. The pooled RR was 0.75 (95% CI, 0.61–0.92) for mortality and 0.73 (95% CI, 0.60–0.88) for poor neurologic/functional outcome at 6 months or hospital discharge (online-only Data Supplement: see Appendix F for forest plots). One additional small RCT of 61 patients evaluated hypothermia in the setting of high-volume hemofiltration and found no increase in survival at 6 months. This study was downgraded for potential confounding because patients received concomitant hemofiltration with high volumes of cold fluid, and this trial was therefore not included in the meta-analysis.

**OHCA With an Initial Nonshockable Rhythm**

Three cohort studies including a total of 1,034 patients provided overall very low-quality evidence for no difference in poor neurologic outcome in patients with nonshockable OHCA (adjusted pooled OR, 0.90 [95% CI, 0.45–1.82]; forest plot in Appendix F of the online-only Data Supplement). One additional retrospective study using a large registry, analyzing 1,830 patients, provided very low-quality evidence for an increase in poor neurologic outcome in patients with nonshockable OHCA (adjusted OR 1.44 [95% CI, 1.04–2.01]). These data were not pooled with the above studies due to very high risk of bias (inconsistent results with different
analyses reported from the study). One of these studies reported mortality and provided overall very low-quality evidence for decreased mortality at 6 months (adjusted OR, 0.56; 95% CI, 0.34–0.93).  

**In-hospital Cardiac Arrest**

One retrospective cohort study of 8,316 IHCA patients with any initial rhythm provided overall very low-quality evidence for no difference in mortality at hospital discharge (adjusted OR, 1.11; 95% CI, 0.81–1.54) or poor neurologic outcome (adjusted OR, 1.08; 95% CI, 0.76–1.54).  

**Evidence for an Ideal Temperature When Using Targeted Temperature Management?**

One RCT of 939 patients compared target temperatures of 33°C and 36°C in adult patients with OHCA of any initial rhythm except unwitnessed asystole. This study provided moderate-quality evidence for no decrease in mortality at 180 days (RR, 1.01; 95% CI, 0.88–1.16) or poor neurologic outcome at 6 months (RR, 1.03; 95% CI, 0.91–1.16) in the 33°C compared with the 36°C group. One additional small pilot RCT of 36 patients compared 32°C and 34°C in patients with OHCA and an initial shockable rhythm or asystole. This study provides overall very low-quality evidence for decreased mortality with 32°C compared with 34°C (RR, 0.63; 95% CI, 0.40–0.97) but no decrease in poor neurologic outcome (RR, 0.64; 95% CI, 0.38–1.09) or increase in survival free from severe dependence (RR, 0.32; 95% CI, 0.08–1.37). However, given the very small sample size, the findings of this study are very imprecise.
Conclusions

One RCT and 1 quasi-RCT provide overall low-quality evidence to use targeted temperature management after ROSC from OHCA with an initial shockable rhythm. Although there is no direct evidence supporting this therapy in nonshockable OHCA or IHCA, indirect evidence extrapolated from studies of shockable OHCA may support this strategy. There is no good direct evidence that suggests that one target temperature within the 32°C to 36°C range is superior to another.

Recommendations

We recommend targeted temperature management as opposed to no targeted temperature management for adults with OHCA with an initial shockable rhythm who remain unresponsive after ROSC (strong recommendation, low-quality evidence).

We suggest targeted temperature management as opposed to no targeted temperature management for adults with OHCA with an initial nonshockable rhythm (weak recommendation, very low-quality evidence) who remain unresponsive after ROSC.

We suggest targeted temperature management as opposed to no targeted temperature management for adults with IHCA (weak recommendation, very low-quality evidence) with any initial rhythm who remain unresponsive after ROSC.

We recommend selecting and maintaining a constant, target temperature between 32°C and 36°C for those patients in whom temperature control is used (strong recommendation, moderate-
quality evidence). Whether certain subpopulations of cardiac arrest patients may benefit from lower (32°C–34°C) or higher (36°C) temperatures remains unknown, and further research may help elucidate this.

**Question #2: Does Early (Prehospital) Induction of Targeted Temperature Management Affect Outcome?**

**Evidence**

Seven RCTs were identified for inclusion from 2,286 studies generated from the search (online-only Data Supplement: see Appendix B for study selection flow diagram). Five\textsuperscript{29-33} of the 7 studies used cold intravenous fluids after ROSC to induce hypothermia, 1 study used cold intravenous fluid during resuscitation\textsuperscript{34} and 1 study\textsuperscript{35} used intra-arrest intranasal cooling. The volume of cold fluid ranged from 20 to 30 mL/kg and up to 2 L though some patients did not receive the full amount prior to hospital arrival. One small feasibility trial was not included.\textsuperscript{36} All 7 included studies suffered from the unavoidable lack of blinding of the clinical team, and 3 also failed to blind the outcomes assessors (online-only Data Supplement: see Appendices C, D, and E for study overview, bias assessments, and GRADE tables).

Five of the studies, enrolling a total of 1,867 patients with OHCA, evaluated the outcome of poor neurologic outcome. Meta-analysis of these studies showed that initiation of induced hypothermia in the prehospital environment did not differ from no initiation of prehospital induced hypothermia for poor neurologic outcome (RR, 1.00; 95% CI, 0.95–1.06). All 7 trials examined the outcome of mortality, and meta-analysis of the total of 2,237 patients provided moderate-quality evidence demonstrating no overall difference in mortality for patients treated with prehospital cooling (RR, 0.98; 95% CI, 0.92–1.04) compared to those who did not receive...
prehospital cooling. Forest plots are presented in Appendix F of the online-only Data Supplement. When reviewed individually, none of the trials found an effect on either poor neurologic outcome or mortality.

Meta-analysis of 4 RCTs that examined the outcome of re-arrest demonstrated an increased risk for re-arrest among patients who received prehospital induced hypothermia (RR, 1.22; 95% CI, 1.01–1.46). This result was driven by data from the largest trial. Six trials included pulmonary edema as an outcome. Three of these recorded no pulmonary edema in either group. The remaining three did record patients who had pulmonary edema. Two small pilot trials found no statistically significant difference between the groups whereas the larger trial by Kim et al found an increase in pulmonary edema in patients who received prehospital cooling (RR, 1.34; 95% CI, 1.15–1.57). Forest plots are presented in Appendix F of the online-only Data Supplement.

Conclusions

In 7 RCTs, providing overall moderate-quality evidence, prehospital induction of mild hypothermia did not reduce poor neurologic outcome or mortality after OHCA. The largest study found an increased risk of pulmonary edema and re-arrest with prehospital induction of mild hypothermia using rapid infusion of cold intravenous fluid.

Recommendation

We recommend against routine use of prehospital cooling with rapid infusion of large volumes of cold intravenous fluid immediately after ROSC (strong recommendation, moderate-quality evidence). Other cooling strategies and cooling during cardiopulmonary resuscitation in the
prehospital setting have not been studied adequately, and further research in this area is needed.

**Question #3: Does the Duration of Targeted Temperature Management Affect Outcome**

**Evidence**

We found no human interventional studies comparing different durations of targeted temperature management after cardiac arrest with ROSC ([online-only Data Supplement](#): see Appendix B for study flow chart). One observational study provided overall very low-quality evidence for no difference in duration of hypothermia in those with a good versus a poor neurologic outcome\(^{37}\) and 1 observational study provided overall very low-quality evidence for no difference in mortality or poor neurological outcome with 24 hours compared with 72 hours of hypothermia\(^ {38}\) ([online-only Data Supplement](#): see Appendices C and D for study overview and bias assessment). Previous trials for targeted temperature management ranged from 12 to 28 hours depending on the trial. One trial (Nielsen et al\(^ {12}\)) provided strict normothermia (<37.5°C) after rewarming until 72 hours after ROSC. However this intervention was applied to both groups and therefore treatment effect cannot be assessed.

**Conclusion**

There are no data that can be used to compare different durations of targeted temperature management in humans.

**Recommendation**

We suggest that if targeted temperature management is used, duration should be at least 24 hours as done in the 2 largest previous RCTs (weak recommendation, very low-quality evidence).\(^ {8,12}\)
Discussion and Knowledge Gaps

Although some recent reports suggest modest improvements in outcome over the past decade, cardiac arrest continues to be associated with high morbidity and mortality.2 The recommendations within this statement should be viewed in light of the very poor prognosis in this patient population and the fact that there are currently very few proven interventions for patients after cardiac arrest. The execution of well-controlled RCTs in post-cardiac arrest patients is challenging due to the complexity, heterogeneity, and high acuity of the patients. Moreover, the inability to blind clinicians to treatments such as temperature management adds an additional layer of difficulty when weighing the evidence.

The most notable difference between the trials by Bernard et al9 and the Hypothermia After Cardiac Arrest (HACA) group8 (both published in 2002) compared with the trial by Nielsen et al12 (published in 2013) is that the earlier studies did not adequately control temperature in the control arm. Average temperatures were >37°C in the control groups in both the study by Bernard et al and the HACA group, whereas tight control was maintained in the 36°C group in the trial by Nielsen et al. Although there is no high-quality evidence, some observational studies have found an association between post-cardiac arrest fever and poor outcome.41-47

The second notable difference between the Bernard et al and HACA trials compared with the trial by Nielsen et al was the use of a blinded neurologic prognosticator instead of reliance on unblinded clinical teams. For both Bernard et al and the HACA investigators, clinical teams aware of the treatment allocation provided families with the prognostic information that informed decisions regarding withdrawal of care; moreover, the timing of prognosis and decision-making was not controlled for. In contrast, Nielsen et al minimized this bias by having
neurologists blinded to the treatment allocation evaluate the patient at 72 hours and provide 
prognostic information at that time. Of note, none of the studies provided information on whether 
the total dosage of preceding sedation was different in the 2 allocation groups at the time of 
neuroprognostication.

Although the results of the trial by Nielsen et al\textsuperscript{15} suggest that controlling temperature at 33°C is not superior to strict temperature control at 36°C, whether this is true for patients who differ from the patient population included in the study is not entirely clear. Patients in the trial by Nielsen et al had higher rates of bystander cardiopulmonary resuscitation than were seen in the HACA trial, for example, (73\% compared with 43\%–49\%). Median no-flow time in patients receiving bystander cardiopulmonary resuscitation was short in the trial by Nielsen et al but this parameter was not reported in other post-cardiac arrest trials and therefore is not comparable. The possibility remains that some unidentified subgroups of patients may benefit from a specific target temperature. We ultimately recommend targeted temperature management at a constant temperature within the range of 32°C to 36°C (the temperature range used in published studies) for comatose post-cardiac arrest patients. Although we recommend that a constant temperature should be maintained during TTM, we also recognize that potential side effects may appropriately lead a clinician to adjust from a lower to higher target temperature despite no direct evidence for this approach. For example, if overt bleeding were to occur at a temperature of 32°C, then one may decide to increase the target temperature to theoretically mitigate this potential side effects. The weaknesses in existing studies illustrate potential knowledge gaps and areas for future research. Of note, the recommendation to control temperature post-cardiac arrest is distinct from mere prevention or treatment of fever which has not been studied in any of the randomized controlled trials.
With respect to the timing of targeted temperature management, the main confounder for the majority of analyzed RCTs is the rapid uncontrolled infusion of a large volume of cold fluid (as opposed to other cooling methods) immediately after ROSC for OHCA. This method for cooling was used for all of the pooled studies with the exception of 1 relatively small pilot study that provided intranasal cooling. The trials using cold fluid specified either amounts up to 2 L or 20 to 30 mL/kg, although not all patients received the full amount prior to hospital arrival. The rapid infusion of large amounts of cold fluid immediately after achieving ROSC and in the prehospital setting could theoretically be harmful, as indicated by increased rates of re-arrest and pulmonary edema in the largest of the included studies, and could therefore negate any potential benefits of early targeted temperature management. Whether similar issues exist with rapid cold fluid infusion in the in-hospital setting is unknown; however, any potential harm from this therapy may relate specifically to the prehospital setting, where there may be less control over the environment, fewer personnel, and reduced monitoring capabilities. We recommend against the use of rapid infusion of large volumes of cold fluid immediately after ROSC for induction of hypothermia in the prehospital setting but recognize that other cooling methods were not adequately evaluated and therefore are not commented on. Thus, further investigation of cooling methods and location may be warranted.

Finally, evidence for a specific duration of targeted temperature management is lacking. In the absence of evidence, we believe that choosing a duration of therapy similar to previous RCTs in targeted temperature management is the most appropriate approach. Human studies specifically focused on different durations have not been performed, and this remains a knowledge gap.

There are many knowledge gaps, and we suggest the following key questions for future research:
• Are there subpopulations in which aggressive prevention of fever instead of targeted
  temperature management (32°C–36°C) is justified?
• Are there subpopulations in which a temperature of 32°C to 34°C is beneficial compared
  with 36°C? For example, are patients with more severe neurologic injury more likely to
  benefit from a lower target temperature?
• Are there subpopulations in which a temperature of 36°C is beneficial compared with
  32°C to 34°C, such as patients with hemodynamic instability or bleeding?
• Is there utility in intra-arrest cooling or prehospital cooling (to between 32°C and 36°C)
  by means other than the rapid infusion of large volumes of cold intravenous fluids
  immediately after ROSC? Might this be helpful in patients for whom transport time to a
  hospital is longer than average (ie, patients in rural areas)?
• What is the ideal duration of targeted temperature management and of fever prevention?
• Does use of targeted temperature management, including various temperature targets,
  have an effect on long term neurocognitive and functional outcomes?
• Does the choice of sedation particularly with respect to different targeted temperatures
  impact or influence outcome?
• What are the reasons for the discrepancy between experimental/animal data and human
  clinical trials on the effects of targeted temperature management?

Summary Recommendations

Based on the published evidence to date, the ALS Task Force of ILCOR made the following
recommendations in February 2015:
• We recommend targeted temperature management as opposed to no targeted temperature management for adults with OHCA with an initial shockable rhythm who remain unresponsive after ROSC (strong recommendation, low-quality evidence).

• We suggest targeted temperature management for adults with OHCA with an initial nonshockable rhythm who remain unresponsive after ROSC (weak recommendation, low-quality evidence).

• We suggest targeted temperature management for adults with IHCA with any initial rhythm who remain unresponsive after ROSC (weak recommendation, very low-quality evidence).

• We recommend selecting and maintaining a constant target temperature between 32°C and 36°C for those patients in whom targeted temperature management is used (strong recommendation, moderate-quality evidence).

• We recommend against routine use of prehospital cooling with rapid infusion of large volumes of cold intravenous fluid immediately after ROSC (strong recommendation, moderate-quality evidence).

• We suggest that if targeted temperature management is used, duration should be at least 24 hours as done in the 2 largest previous RCTs.
Acknowledgments

We would like to acknowledge Christine Neilson and the team at St Michael’s Hospital in Toronto for their literature searches.

This table represents the relationships of writing group members that may be perceived as actual or reasonably perceived conflicts of interest as reported on the Disclosure Questionnaire, which all members of the writing group are required to complete and submit. A relationship is considered to be “significant” if (a) the person receives $10,000 or more during any 12-month period, or 5% or more of the person’s gross income; or (b) the person owns 5% or more of the voting stock or share of the entity, or owns $10,000 or more of the fair market value of the entity. A relationship is considered to be “modest” if it is less than “significant” under the preceding definition.

Appendix B: Selection of Articles

Question #1:

OHCA indicates out-of-hospital cardiac arrest; RCT: randomized controlled trial.
**Question #2:**

Records identified through database search (n = 3015)

Additional records identified through other sources (n = 0)

Records after duplicates removed (n = 2286)

Records screened (n = 2286)  Records excluded (n = 2278)

Full-text articles assessed for eligibility (n = 8)  Full-text articles excluded (n = 1 small feasibility trial [1])

Studies included in qualitative synthesis (n = 7)

Studies included in quantitative synthesis (meta-analysis)  
(n = 7 for survival)  
(n = 5 for good neurologic outcome)  
(n = 5 for rearrest)  
(n = 6 for pulmonary edema)
Question #3:

Records identified through database search 
(n = 1594)

Additional records identified through other sources 
(n = 0)

Records after duplicates removed 
(n = 1253)

Records screened 
(n = 1253)

Records excluded 
(n = 1251)

Full-text articles assessed for eligibility 
(n = 2)

Full-text articles excluded 
(n = 0)

Studies included in qualitative synthesis 
(n = 2)

Studies included in quantitative synthesis (meta-analysis) 
(n = 0)

</table>
| HACA (2002)[11] | 275 | 3551 | Age 18–75 y, OHCA, witnessed arrest, initial shockable rhythm, presumed cardiac origin, collapse-to-CPR interval >5 to <15 min, collapse-to-ROSC interval <60 min | Initial temperature <30°C, pre–cardiac arrest coma, pregnancy, following commands, hypotension >30 min, severe hypoxia >15 min, pre–cardiac arrest terminal illness, unlikely to follow up, concomitant enrollment in another study, EMS-witnessed arrest, preexisting coagulopathy | Surface cooling to 32°C to 34°C within 4 h of ROSC, maintenance for 24 h, then passive rewarming | Normothermia (not otherwise defined) | Good neurologic status at 6 mo (CPC 1–2) | 55% vs 39% (P=0.009)
| Bernard et al. (2002)[12] | 77 | 84 | OHCA, initial shockable rhythm, persistent coma | Female age <50 y and male age <18 y, systolic blood pressure <90 mm Hg despite vasopressor support, other possible causes of coma, unavailable ICU bed at hospital | Prehospital initiation of surface cooling to 33°C after ROSC, maintenance for 12 h, then active rewarming for 6 h | Target core temperature of 37°C, passive rewarming if spontaneously hypothermic | Good functional status at hospital discharge (discharge to home or acute rehabilitation) | 49% vs 26% (P=0.046)
| Laurent et al. (2005)[13] | 61 | 244 | Age 18–75 y, OHCA, initial shockable or asystolic rhythm, collapse-to-CPR <10 min, collapse-to-ROSC <50 min, presumed cardiac origin | Pregnancy, following commands, preexisting terminal illness | Hemofiltration plus active cooling with replacement fluid to 32°C to 33°C for 24 h, then passive rewarming | Hemofiltration with replacement fluid set to 37°C | Mortality at 6 mo | 32% vs 45% (P=0.28) |
| Zhang et al. (2005)[14] | 16 | Not reported | Received CPR for cardiac arrest | Previous history of cardiac arrest, trauma | Surface cooling to 33°C for 72 h, then rewarming at 1°C/h | No temperature management | Secondary outcome: functional status at 3 mo | Barthel Index score: 86±6 vs 52±12 (P<0.01) |
| Study                          | n  | N/A | Age >18 y, nontraumatic OHCA in a registry, witnessed, initial nonshockable rhythm | Died <24 h after ROSC, GCS >8, prearrest CPC 3–5, CVA cause of arrest, initial temperature <30°C | Cooling via any method as rapidly as possible to 36°C, maintenance for 28 h, then rewarming at maximum 0.5°C/h to 37°C, then active fever prevention until 72 h after the cardiac arrest | All-cause mortality through the end of the trial | 50% vs 48% (P=0.51) | Hazard ratio 1.06 (95% CI, 0.89–1.28) |
|-------------------------------|----|-----|----------------------------------------------------------------------------------|-----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------
| Lopez-de-Sa et al. (2012)[15] | 36 | 73  | Age >18 y, OHCA, witnessed arrest, presumed cardiac cause, initial shockable or asystolic rhythm, collapse-to-ROSC ≤ 60 min | GCS >8, pregnancy, initial PEA rhythm, preceding terminal illness, other possible causes of coma, shock despite 30 min of administration of inotropes | Induction with ice-cold crystalloid and maintenance of 32°C with endovascular device for 24 h, then rewarming at 0.1°C to 0.3°C/h | Good functional status at 6 mo (Barthel Index score ≥60) | 44% vs 11% (P=0.12) |  |
| Nielsen et al. (2013)[16]     | 939| 1431| OHCA, any initial rhythm, GCS <8 Obvious or suspected pregnancy, known bleeding diathesis, suspected or confirmed acute intracranial bleeding or acute stroke, unwitnessed cardiac arrest with initial rhythm asystole, known limitations in therapy and do-not-resuscitate order, known disease that would make 180-d survival unlikely, known prearrest CPC 3 or 4, >4 h from ROSC to screening, systolic blood pressure <80 mm Hg in spite of fluid loading/vasopressor and/or inotropic medication/ intra-aortic balloon pump, temperature on admission <30°C | Cooling via any method as rapidly as possible to 33°C, maintenance for 28 h, then rewarming at maximum 0.5°C/h to 37°C, then active fever prevention until 72 h after the cardiac arrest | Cooling via any method as rapidly as possible to 36°C, maintenance for 28 h, then rewarming at maximum 0.5°C/h to 37°C, then active fever prevention until 72 h after the cardiac arrest | All-cause mortality through the end of the trial | 50% vs 48% (P=0.51) | Hazard ratio 1.06 (95% CI, 0.89–1.28) |

Observational studies

| Study                          | n  | N/A | Age >18 y, nontraumatic OHCA in a registry, witnessed, initial nonshockable rhythm | Died <24 h after ROSC, GCS >8, prearrest CPC 3–5, CVA cause of arrest, initial temperature <30°C | Cooling via any method as rapidly as possible to 32°C to 34°C for 24 h | No temperature management | Good functional status at 6 mo (CPC 1–2) | 35% vs 23% (P=0.02) | Adjusted OR 1.84 (95% CI, 1.08–3.13) |
|-------------------------------|----|-----|----------------------------------------------------------------------------------|-----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------
<p>| Testori et al. (2011)[17]     | 374| N/A | Age &gt;18 y, nontraumatic OHCA in a registry, witnessed, initial nonshockable rhythm | Died &lt;24 h after ROSC, GCS &gt;8, prearrest CPC 3–5, CVA cause of arrest, initial temperature &lt;30°C | Cooling via any method as rapidly as possible to 32°C to 34°C for 24 h | No temperature management | Good functional status at 6 mo (CPC 1–2) | 35% vs 23% (P=0.02) | Adjusted OR 1.84 (95% CI, 1.08–3.13) |
| Dumas et al. (2011)[18]       | 437| N/A | OHCA patients in a registry, initial nonshockable rhythm | Trauma | Surface cooling to 32°C to 34°C for 24 h, then passive rewarming for additional 24 h | No temperature management | Good functional status at hospital discharge (CPC 1–2) | 15% vs 17% (P=0.48) | Adjusted OR 0.71 (95% CI, 0.37–1.36) |</p>

*High risk of residual confounding.
†Patients with traditional targeted temperature management exclusion criteria not excluded before analysis.
‡Less than 3% of subjects received hypothermia, and inclusion criteria rely solely on coding in the registry.
§Independent documentation of therapeutic temperature was available for only 40% of patients cooled and was not always consistent with reaching target temperature for those reportedly cooled. Less than 3% of patients received the intervention, which causes high concern for confounding by indication.
**Limited data on how decision to use hypothermia was made
*No actual temperature data; exclusion criteria rely solely on coding in the registry
**Question #2:**

</tbody>
</table>

CI indicates confidence interval; OHCA, out-of-hospital cardiac arrest; RCT, randomized controlled trial; ROSC, return of spontaneous circulation; RR, risk ratio; TTM, targeted temperature management.

*Includes assessment of publication bias, magnitude of the effect, dose-response gradient, and plausible residual confounding leading to spurious effect when no effect was observed or reduction of a demonstrated effect.

†The risk ratios represent the risk of the outcome in the treatment group (targeted temperature management) compared to the control group (no targeted temperature management) such that a risk ratio <1 indicates the outcome being less common in the intervention group. When more than 1 trial is included the pooled risk ratio is reported. See appendix F for forest plots.

‡Absolute effect is calculated as the absolute difference in the outcome between the treatment group (targeted temperature management) and the control group (no targeted temperature management) expressed as number of patients per 1000 patients treated. For the confidence interval, positive numbers reflect more patients and negative numbers fewer patients with the outcome.

§Neurological prognosticators and clinical team not blinded.

‖One of the included trials used quasi-randomization (alternating days).[12] We did not consider this to introduce enough additional concern to increase the overall risk of bias to “very serious”.

¶Optimal information size not achieved. Based on a conservative alpha of 0.01, beta of 0.2, a control outcome rate of 55% and a relative risk reduction of 10% the optimal information size was calculated at 3,922 total patients.

#Simultaneous hemofiltration.

**Poor neurological/functional outcome defined as a cerebral performance category score of 3, 4 or 5 or dead[11] or not being discharged home or to rehabilitation.[12]
TTM compared with no TTM in adults with OHCA with an initial nonshockable rhythm who remain unresponsive after ROSC

CI, confidence interval; NA, not available; NE, not estimable; OHCA, out-of-hospital cardiac arrest; OR, odds ratio; ROSC, return of spontaneous circulation; TTM, targeted temperature management.

*Include assessment of publication bias, magnitude of the effect, dose-response gradient, and plausible residual confounding leading to spurious effect when no effect was observed or reduction of a demonstrated effect.

†Adjusted ORs are reported for mortality. For the outcome of poor neurologic outcome the pooled OR was used (see Appendix F for forest plot). The ORs represent the risk of the outcome in the treatment group (TTM) compared with the control group (no TTM) adjusted for various confounders.

‡Absolute effect is calculated as the absolute difference in the outcome between the treatment group (TTM) and the control group (no TTM) calculated based on the control group risk and the adjusted OR, expressed as number of patients per 1000 patients treated. For the CI, positive numbers reflect more patients and negative numbers fewer patients with the outcome.

§High risk of residual confounding.

‖Optimal information size not achieved. Based on a conservative α of 0.01, a β of 0.2, a control outcome rate of 75%, and a relative risk reduction of 10%, the optimal information size was calculated at 1748 total patients.

¶Poor neurologic outcome defined as a cerebral performance category score of 3, 4, or 5 or dead.

#CI cannot exclude clinically relevant benefit or harm.

**Very high risk of residual confounding

†† Study reported multiple analyses with inconsistent results

CI indicates confidence interval; OHCA, out-of-hospital cardiac arrest; RCT, randomized controlled trial; ROSC, return of spontaneous circulation; RR, risk ratio; TTM, targeted temperature management.

*Includes assessment of publication bias, magnitude of the effect, dose-response gradient, and plausible residual confounding leading to spurious effect when no effect was observed or reduction of a demonstrated effect.

†The RRs represent the risk of the outcome in the 33°C group compared with the 36°C group.

‡Absolute effect is calculated as the absolute difference in the outcome between the treatment group (TTM) and the control group (no TTM) calculated based on the control group risk and the risk ratio, expressed as number of patients per 1000 patients treated. For the CI, positive numbers reflect more patients and negative numbers fewer patients with the outcome.

§The authors also reported the results of a time-to-event analysis (hazard ratio, 1.06 [95% CI, 0.89–1.28]).

‖Although clinicians and patients were not blinded, we do not consider this to introduce enough bias to downgrade the evidence, because the neurologic prognosticators were blinded.

¶CI cannot exclude clinically relevant benefit or harm.

#Poor neurologic outcome defined as a cerebral performance category score of 3, 4, or 5 or dead. The authors also reported poor neurologic outcome, defined as a modified Rankin scale score of 4 to 6 (RR 1.01 [95% CI, 0.89–1.14]).
### 32°C compared with 34°C for adults with OHCA who remain unresponsive after ROSC and receive targeted temperature management

CI, confidence interval; OHCA, out-of-hospital cardiac arrest; RCT, randomized controlled trial; ROSC, return of spontaneous circulation; RR, risk ratio.

*Includes assessment of publication bias, magnitude of the effect, dose-response gradient, and plausible residual confounding leading to spurious effect when no effect was observed or reduction of a demonstrated effect.

†The RRs represent the risk of the outcome in the 32°C group compared with the 34°C group.

‡Absolute effect is calculated as the absolute difference in the outcome between the treatment group (targeted temperature management) and the control group (no targeted temperature management) calculated based on the control group risk and the adjusted odds ratio, expressed as number of patients per 1000 patients treated. For the CI, positive numbers reflect more patients and negative numbers fewer patients with the outcome.

§Neurologic prognosticators not blinded, and risk of confounding caused by unbalanced groups.

‖Optimal information size not achieved. See calculations above.

¶Poor neurologic outcome, defined as the best cerebral performance category score being 3, 4, or 5. The authors also reported death or severe dependence, defined as a Barthel score <60 (RR 0.32 [95% CI, 0.08–1.37]).

#CI cannot exclude clinically relevant benefit or harm.
**Question #2:**

Prehospital targeted temperature management compared with no prehospital targeted temperature management in adults with OHCA who remain unresponsive after ROSC

CI indicates confidence interval; OHCA, out-of-hospital cardiac arrest; RCTs, randomized controlled trials; ROSC, return of spontaneous circulation; RR, risk ratio.

*Includes assessment of publication bias, magnitude of the effect, dose-response gradient, and plausible residual confounding leading to spurious effect when no effect was observed or reduction of a demonstrated effect.

†Pooled RRs are reported for all relative effect measures. The RRs represent the risk of the outcome in the treatment group (prehospital targeted temperature management) compared with the control group (no prehospital targeted temperature management). The corresponding forest plots are presented in Appendix F.

‡Absolute effect is calculated as the absolute difference in the outcome between the treatment group (prehospital targeted temperature management) and the control group (no prehospital targeted temperature management) calculated based on the control group risk and the pooled RR, expressed as number of patients per 1000 patients treated. For the CI, positive numbers reflect more patients and negative numbers fewer patients with the outcome.

§Neurologic prognosticators and clinical team not blinded.

‖Poor neurologic outcome defined as a cerebral performance category score of 3, 4, or 5 or not being discharged home or to rehabilitation

¶Clinical team and outcome assessors not blinded.

#Very large variability in reported incidences.
**Pulmonary edema was assessed with initial radiography[22, 27] or “oxygen desaturation <90% with froth visible in the endotracheal tube” prehospital.[25, 26] Two studies did not report details related to assessment of pulmonary edema.[23, 28] †† No pooled estimate was calculated. See Appendix F.

Heterogeneity: $\tau^2 = 0.23; \chi^2 = 5.27, df = 2 (P = 0.07); I^2 = 62$
Test for overall effect: $Z = 0.28 (P = 0.78)$

*Adjusted odds ratios and inverse variance weighting were used to calculate the pooled odds ratio. The study by Mader et al.[21] was not included in the meta-analysis given the very high risk of bias.
Question #2:

For the study by Castren et al.[24] only patients who had return of spontaneous circulation were included in the meta-analysis. The exclusion of the studies that initiated temperature management during cardiopulmonary resuscitation (Castren et al.[24] and Debaty et al.[28]) did not meaningfully change the pooled risk ratios for any of the outcomes (data not shown).

A. Forest Plot – Outcome: Poor Neurologic Outcome
